Synchronizable Error-Correcting Codes*

R. C. BOSE and J. G. CALDWELL

Department of Statistics, University of North Carolina,
Chapel Hill, North Carolina 27514

A new technique for correcting synchronization errors in the trans-
mission of discrete-symbol information is developed. The technique
 can be applied to any \( t \)-additive-error-correcting Bose-Chaudhuri-
Hocquenghem code, to provide protection against synchronization
errors. The synchronization error is corrected at the first complete
received word after the word containing the synchronization error,
even if this following word contains up to \( t \) additive errors. An exam-
ple is presented illustrating in detail the application of the tech-
nique.

I. INTRODUCTION

In order for digital information to be accurately and efficiently trans-
mitted over a noisy channel, efficient procedures for eliminating or
determining the effect of the noise must be devised. Considerable
research has been performed to determine means to accomplish reliable
transmission in the presence of additive noise, i.e., noise which may
cause transmitted symbols to be altered, or changed into other symbols.
An effective means for coping with additive errors is to employ an addi-
tive-error-correcting code. For channels in which noise affects successive
symbols independently, one of the best among the known classes of
additive-error-correcting codes is the class of Bose-Chaudhuri-Hoe-
quenghem, or BCH, codes.

Whether or not additive errors are of concern in a particular situation,
there may occur a much more serious kind of error. This second type
of error arises due to the fact that the individual symbols of a sequence
of symbols have physical meaning to the receiver only when considered
together with certain other symbols of the sequence. Generally, the

124-G670.
sequence of received symbols must be correctly grouped into "words," or "frames," in order for the receiver to properly understand the message. When noise is such that the receiver incorrectly groups the symbols into words, reception is said to be out of synchronization with transmission, and a synchronization error is said to have occurred. Note that a synchronization error may be considered to be a loss or gain of a certain number of symbols in transmission.

In contrast to the situation for additive errors, research concerned with the development of efficient techniques for synchronization-error correction has been limited. This paper presents a new technique for synchronization-error correction. The technique can be applied to any cyclic additive-error-correcting code, and enables immediate correction of synchronization errors, simultaneously with the correction of additive errors.

Just as BCH codes exist for a range of values of $t$, the number of additive errors allowed per code word, the new synchronization technique can be applied to provide protection against synchronization errors involving a range of symbol losses or gains. If the new technique is chosen so that up to $t_1$ symbol losses can be corrected and up to $t_r$ symbol gains can be corrected, then we say that the code to which the technique is applied is a $t_s$-synchronization-error-correcting code, where $t_s = t_1 + t_r$. If the technique is applied to a $t$-additive-error-correcting BCH code, we call the resulting code a $(t, t_s)$-error-correcting code. The resulting code can simultaneously correct synchronization errors and additive errors, and we refer to such a code as a synchronizable error-correcting code.

Early work concerned with mathematical analysis of the synchronization problem was done by Barker (1953). Recent work aimed at finding synchronizable error-correcting codes has been done by Stiffer (1965), Levy (1966), and Tong (1966). Many others have studied the synchronization problem, and an extensive bibliography of articles relating to synchronization is given by Caldwell (1966).

II. BCH CODES

Because the synchronizable error-correcting codes to be developed later will be based on BCH codes, we shall give here a brief description of these codes. (Bose and Ray-Chaudhuri, 1960a, b; and Hocquenghem, 1959).

Consider a $q$-ary channel, i.e., a channel capable of transmitting $q$
distinct symbols where \( q \) is a prime or the power of a prime. Let the Galois field \( GF(q) \) be extended to \( GF(q^m) \), and let \( \alpha \) be an element of the extended field such that \( 1, \alpha, \alpha^2, \ldots, \alpha^{n-1} \) are all different and \( \alpha^n = 1 \). Then \( n \) is a divisor of \( q^m - 1 \), and if \( \theta \) is a primitive element of \( GF(q^m) \) then \( \alpha = \theta^n \), where \( un = q^m - 1 \). Consider the matrix

\[
H_0 = \begin{bmatrix}
1 & \alpha^{m_0} & (\alpha^{m_0})^2 & \cdots & (\alpha^{m_0})^{n-1} \\
1 & \alpha^{m_0+1} & (\alpha^{m_0+1})^2 & \cdots & (\alpha^{m_0+1})^{n-1} \\
\vdots & \vdots & \vdots & \cdots & \vdots \\
1 & \alpha^{m_0+d-2} & (\alpha^{m_0+d-2})^2 & \cdots & (\alpha^{m_0+d-2})^{n-1}
\end{bmatrix}
\]

Each element of \( GF(q^m) \) can be expressed as a polynomial of degree \( m - 1 \) of the primitive root \( \theta \), the coefficients of the polynomial belonging to \( GF(q) \). Hence any element can be identified with an \( m \)-vector over \( GF(q) \), viz., the coefficient vector of the corresponding polynomial. Hence the matrix \( H_0 \) can be regarded either as a \( (d - 1) \times n \) matrix over \( GF(q^m) \) or as a \( (d - 1) \times mn \) matrix over \( GF(q) \), on identifying the elements of \( GF(q^m) \) with column \( m \)-vectors over \( GF(q) \). In particular the element 1 is identified with the transpose of \((1, 0, 0, \ldots, 0)\). When regarded in this second way, the rank of \( H_0 \) is \( r \leq m(d - 1) \). If \( H \) is the matrix obtained from \( H_0 \) by retaining \( r \) suitably chosen independent rows then it is known, Peterson (1961), that \( H \) is the parity-check matrix of an \((n, k)\) BCH code \( C \), with minimum distance \( d \) and redundancy \( r \), \((k = n - r)\). If \( d = 2t + 1 \), then the code will be \( t \)-error-correcting.

Let \( g_i(x) \) be the minimum function of \( \alpha^i \) over \( GF(q) \), i.e., \( g_i(x) \) is the smallest-degree monic polynomial over \( GF(q) \) which has \( \alpha^i \) for a root. Then the degree of \( g_i(x) \) is a divisor of \( m \), and therefore cannot exceed \( m \). Let

\[
g(x) = \text{L.C.M.} \{g_{m_0}(x), g_{m_0+1}(x), \ldots, g_{m_0+d-2}(x)\},
\]

then \( g(x) \) is the smallest degree monic polynomial over \( GF(q) \) which has roots \( \alpha_{m_0}, \alpha_{m_0+1}, \ldots, \alpha_{m_0+d-2} \), and is the generator polynomial of the BCH code \( C \). The vector \( v' = (v_0, v_1, \ldots, v_{n-1}) \) is a word of \( C \) if and only if the corresponding polynomial \( v(x) = v_0 + v_1x + \cdots + v_{n-1}x^{n-1} \) is a multiple of \( g(x) \); i.e., \( v(x) = g(x)\Phi(x) \) where \( \Phi(x) \) is a polynomial of degree \( k - 1 \) or less over \( GF(q) \). The code \( C \) is cyclic; i.e., if \( v' = (v_0, v_1, \ldots, v_{n-1}) \) is a word of \( C \), then so is \( v'(i) = (v_i, v_{i+1}, \ldots, v_{n-1}, v_0; v_1, \ldots, v_{i-1}) \). The generator polynomial \( g(x) \) is of degree \( r \).
and is a divisor of \(x^n - 1\); i.e., we can find a polynomial \(h(x)\) over \(GF(q)\) such that \(g(x)h(x) = x^n - 1\).

The BCH code \(C\) is said to be primitive if \(u = 1\), i.e., \(\alpha\) is a primitive element of \(GF(q^m)\) and \(n = q^m - 1\).

### III. THE ENCODING PROCEDURE FOR A CLASS OF SYNCHRONIZABLE CODES

Let \(C\) be the BCH code described in Section II, where \(d = 2t - 1\), so that \(C\) is \(t\)-error-correcting. Let \(\beta\) be a root of \(x^n - 1 = 0\) but not a root of \(g(x)\). Thus \(\beta\) is a root of \(h(x)\). Let \(f(x)\) be the minimum function of \(\beta\), i.e., \(f(x)\) is the smallest-degree monic polynomial over \(GF(q)\) which has \(\beta\) for a root. The degree of \(f(x)\) will not exceed \(m\), and will be \(m_1\) where \(m_1\) is a divisor of \(m\). In this case \(\beta\) will belong to a subfield of order \(q^{m_1}\) of the field \(GF(q^m)\). The polynomial \(f(x)\) will be a divisor of \(h(x)\). Let \(n_1\) be the order of \(\beta\), i.e., \(n_1\) is the smallest positive (nonzero) integer such that \(\beta^{n_1} = 1\). Then \(n_1\) is a divisor of \(n\).

Let \(C^*\) be the subcode of \(C\) generated by \(g(x)f(x)\); i.e., the polynomial corresponding to a word of \(C^*\) is divisible by \(g(x)f(x)\). Then \(C^*\) is an \((n, k^*)\) code where \(k^* = n - r - m_1\). Any word \(v' = (v_0, v_1, \cdots, v_{n-1})\) of \(C^*\) satisfies

\[v'[H', H_1] = 0,\]

where \(H\) is the parity-check matrix of \(C\), and

\[H_1 = [1, \beta, \beta^2, \cdots; \beta^{n_1-1}].\]

As before, \(H_1\) may be regarded as either a row vector over \(GF(q^m)\) or an \(m \times n\) matrix over \(GF(q)\).

Let \(c' = (c_0, c_1, \cdots, c_{n-1})\) be a fixed nonnull word of \(C\), which does not belong to the subcode \(C^*\). Let \(t_s = t_1 + t_r < n_1\) (the order of \(\beta\)). It is our objective to construct a code which can correct a shift of order up to \(t_1\) to the left or a shift of order up to \(t_r\) to the right. Since \(t_s > 0\), the requirement \(t_s < n_1\) implies \(n_1 > 1\). Thus \(\beta \neq 1\). Corresponding to \(v'\) and \(c'\), we now take augmented words

\[v_a' = (v_{n-t_r}, \cdots, v_{n-1}; v_0, v_1, \cdots, v_{n-1}; v_0, v_1, \cdots, v_{t_1-1}),\]

\[c_a' = (c_{n-t_r}, \cdots, c_{n-1}; c_0, c_1, \cdots, c_{n-1}; c_0, c_1, \cdots, c_{t_1-1}).\]

Thus we buffer \(v'\) by cyclically adding \(t_r\) symbols to the left and \(t_1\) symbols to the right of \(v'\). A similar procedure is adopted for buffering \(c'\). We now consider a new code \(C_a\) whose words are \(v_a' + c_a'\). The words
of $C_n$ are in $1, 1$ correspondence with the words of $C^*$. Hence the number of message sequences is the same as for $C^*$, viz., $q^*$. When we want to send a message corresponding to the word $v'$ of $C^*$ we shall actually transmit $v_a' + c_a'$. The length of the new code is $n_a = n + t_r + t_l$, and the number of information places is $k_a = k^* = n - r - m_1$. Hence the redundancy is $r_a = r + t_n + m_1$, where $t_n = t_r + t_l$ is the sum of the orders of the maximum shifts to the right and left which are to be corrected.

IV. THE DECODING PROCEDURE

Suppose $v_a' + t_a'$ is transmitted, and the additive-error vector is $e_a' = (f_{n-t_r}, \ldots, f_{n-1}, e_0, e_1, \ldots, e_{n-1}, f_0, f_1, \ldots, f_{t_l-1})$. Thus the received vector will be

$$y_a' = v_a' + c_a' + e_a',$$

if there is no shift error. If there is a shift of $L$ places to the left, $L \leq t_1$, then $L$ of the initial symbols of $y_a'$ will go over to the previous word, and the received word will contain in the end $L$ symbols from the beginning of the succeeding word. Similarly if there is a shift of $R$ places to the right, $R \leq t_r$, then $R$ of the end symbols of $y_a'$ will be shifted to the subsequent word, and in the beginning of the received word we will have $R$ symbols from the end of the previous word. The decoding proceeds step by step as follows:

Step I. We form the truncated received word $y'$ by dropping the first $t_r$ and the last $t_l$ symbols of the received word $y_a'$. The truncated received word is of length $n$. Note that the symbols dropped are just those which in an extreme case under the permissible synchronization errors could have come from a previous or a subsequent word. We now consider three cases separately.

Case (i). If there are no synchronization errors the truncated received word will be

$$y' = (v_0, v_1, \ldots, v_{n-1}) + (c_0, c_1, \ldots, c_{n-1}) + (e_0, e_1, \ldots, e_{n-1})$$

$$= v' + c' + e'.$$

Case (ii). If there is a left shift of $L \leq t_1$ places, then the truncated
received word will be
\[ y' = (v_L, v_{L+1}, \ldots, v_{n-1}, v_0, \ldots, v_{L-1}) + (c_L, c_{L-1}, \ldots, c_{n-1}, c_0, c_1, \ldots, c_{L-1}) + (e_L, e_{L+1}, \ldots, e_{n-1}, f_0, f_1, \ldots, f_{L-1}) \]
\[ = \nu'(L) + c'(L) + e'_L. \]

where we use the notation \( \nu'(i) \) to denote \( (v_i, v_{i-1}, \ldots, v_{n-1}, v_0, v_1, \ldots, v_{i-1}) \).

Case (iii). Similarly, if there is a right shift of \( R \leq t \) places, then the truncated received word will be
\[ y' = (v_{n-R}, \ldots, v_{n-1}, v_0, v_1, \ldots, v_{n-R-1}) + (c_{n-R}, \ldots, c_{n-1}, c_0, c_1, \ldots, c_{n-R-1}) + (e_{n-R}, \ldots, e_{n-1}, e_0, e_1, \ldots, e_{n-R-1}) \]
\[ = \nu'(n - R) + c'(n - R) + e'_{n-R}. \]

**Step II.** We form the additive-error syndrome \( y'H' \). Note that from the cyclic nature of BCH codes, \( \nu', \nu'(L) \) or \( \nu'(n - R) \) in cases (i), (ii), and (iii), respectively, will belong to the code \( C \). Similarly \( c', c'(L) \), or \( c'(n - R) \) will belong to the \( C \). Hence
\[ y'H' = e'H', \text{ in case (ii)}, \]
\[ y'H' = e'_L'H', \text{ in case (ii)}, \]
\[ y'H' = e'_{n-R}H', \text{ in case (iii)}. \]

By assumption, the number of additive errors is less than or equal to \( t \), so that \( wt(e'_a) \leq t \). Consequently \( wt(e'_L), wt(e'_{n-R}) \) will be less than or equal to \( t \). Then as for BCH codes there will be a \((1, 1)\) correspondence between the error vector and the syndrome. Hence the error vector can be determined by using any error-correction procedure for \( t \)-error correcting BCH codes.

**Step III.** The received truncated word \( y' \) is now corrected for additive errors by subtracting the determined error vector \( e'_a, e'_L, \) or \( e'_{n-R} \).
We thus obtain
\[ z' = v' + c' \text{ in case (i)}, \]
\[ z' = v'(L) + c'(L) \text{ in case (ii)}, \]
\[ z' = v'(n - R) + c'(n - R) \text{ in case (iii)}. \]
Step IV. We now form the shift-error syndrome $z'H_1'$. Since from our method of formation, the subcode $C^*$ is also a cyclic code, $v'(L)$ and $v'(n - R)$ belong to $C^*$ in cases (ii) and (iii), respectively.

Hence we obtain

$z'H_1' = c'H_1'$ in case (i),

$z'H_1' = c'(L)H_1'$ in case (ii),

$z'H_1' = c'(n - R)H_1'$ in case (iii).

Since the order of $\beta$ is $n_1$, a divisor of $n$, we have $\beta^{n_1} = 1, \beta^n = 1$. Also $1, \beta, \beta^2, \cdots, \beta^{n_1-1}$ are all different. Now

$$c'H_1' = c_0 + c_1\beta + c_2\beta^2 + \cdots + c_{n-1}\beta^{n-1} = \zeta,$$

where $\zeta$ is a known element of $GF(q^m)$, since $c'$ and $\beta$ are known. Again,

$$c'(L)H_1' = c_L + c_{L+1}\beta + c_{L+2}\beta^2 + \cdots + c_{L-1}\beta^{n-1} = \beta^{L-1}\zeta = \beta^{n_1-L}\zeta,$$

$$c'(n - R)H_1' = c_{n-R} + c_{n-R+1}\beta + c_{n-R+2}\beta^2 + \cdots + c_{n-R-1}\beta^{n-1} = \beta^{R-L}\zeta.$$

Step V. Divide the shift-error syndrome by the known element $\zeta$, obtaining 1, $\beta^{n_1-L}$, $\beta^R$ in cases (i), (ii), and (iii), respectively. Now $1 \leq L \leq t_1, 1 \leq R \leq t_r$, and by supposition $t_u = t_r + t_1 < n_1$. Hence $n_1 - L > t_r$. Thus if the answer in step V is 1, we conclude that there is no shift error. If the answer in step V is $\beta^u$ where $u > t_r$ we conclude that a left shift of order $L = n_1 - u$ has occurred. Again, if $1 \leq u \leq t_r$, we conclude that a right shift of order $R = u$ has occurred.

We can now correct $z'$ by applying the reverse shift, and obtain $v' + c'$. Finally, by subtracting $c'$ we obtain $v'$, the word of $C^*$ which corresponds to the message sent.

It should be remembered that in applying this procedure, synchronization errors can be corrected at the word following that where information symbols have been lost or gained, and not in the damaged word itself.

V. EXAMPLE

APPLICATION OF THE TECHNIQUE TO A BCH BINARY CODE OF LENGTH $n = 15$

To illustrate the new synchronization technique, we shall consider the BCH code of length $n = 2^m - 1 = 2^4 - 1 = 15$ which originally was
SYNCHRONIZABLE ERROR-CORRECTING CODES

TABLE 1

Nonzero Elements of \( GF(2^4) \), Expressed as Powers of the Root \( \alpha = (0, 1, 0, 0) \) of the Minimum Function \( g_1(x) = x^4 + x + 1 \)

| \( \alpha^0 \) | \( \alpha = x \) | \( \alpha^2 = x^2 \) | \( \alpha^3 = x^3 \) | \( \alpha^4 = 1 + x \) | \( \alpha^5 = x + x^2 \) | \( \alpha^6 = x^2 + x^3 \) | \( \alpha^7 = 1 + x + x^3 \) | \( \alpha^8 = 1 + x^3 \) | \( \alpha^9 = x + x^4 \) | \( \alpha^{10} = 1 + x + x^3 \) | \( \alpha^{11} = x + x^3 + x^4 \) | \( \alpha^{12} = 1 + x + x^3 + x^4 \) | \( \alpha^{13} = 1 + x^3 + x^4 \) | \( \alpha^{14} = 1 + x^3 \) |
|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|

The polynomial expression for each power of \( \alpha \) is obtained by using the relation \( \alpha = x, x^4 = x + 1 \).

Presented by Bose and Ray-Chaudhuri (1960a). Over the coefficient field \( GF(2) \) we have the factorization

\[
x^{15} - 1 = g_1(x)g_2(x)g_3(x)g_7(x)(x + 1)
\]

\[
= (x^4 + x + 1)(x^4 + x^3 + x^2 + x + 1)(x^2 + x + 1)
\]

\[
\cdot (x^4 + x^3 + 1)(x + 1),
\]

where \( g_i(x) \) denotes the minimum function of \( \alpha^i \). We choose

\[
g(x) = g_1(x)g_3(x)
\]

\[
= (x^4 + x + 1)(x^4 + x^3 + x^2 + x + 1)
\]

\[
= 1 + x^4 + x^6 + x^7 + x^8
\]

for the generator polynomial of the code \( C \). The code \( C \) is an \( (n, k) = (15, 7) \) code. The Galois field \( GF(2^4) \) is based on the primitive polynomial \( g_1(x) = x^4 + x + 1 \). All the nonzero elements of \( GF(2^4) \) can thus be written as powers of the root \( \alpha = (0, 1, 0, 0) \) of \( g_1(x) \), and they are shown in Table 1. The zero element is, of course, \( (0, 0, 0, 0) \). The roots
of the primitive polynomial \( g_1(x) \) are
\[
\alpha, \alpha^2, \alpha^4, \alpha^8,
\]
and the roots of \( g_2(x) \) are
\[
\alpha^3, \alpha^6, \alpha^{12}, \alpha^{24} = \alpha^9.
\]
Thus,
\[
\alpha, \alpha^2, \alpha^3, \alpha^4, \alpha^5, \alpha^6, \alpha^8, \alpha^9, \alpha^{12}
\]
are all the roots of \( g(x) \), and the code is \((t = 2)\)-additive-error-correcting, since the first \(2t = 2 \cdot 2 = 4\) successive powers of \( \alpha \) are roots of \( g(x) \).

To use the new synchronization technique, we must choose \( \beta = \alpha^j \neq 1 \) such that \( \beta \) is not a root of \( g(x) \). Equivalently, we must choose for \( f(x) \) a minimum function \( g_\beta(x) \neq x - 1 \) such that \( g_\beta(x) \) is not a factor of \( g(x) \). Now the factors of \( x^{15} - 1 \) other than \( (x - 1)g(x) \) are \( g_5(x) \) and \( g_7(x) \). The factor \( g_5(x) \) has roots \( \alpha^5 \) and \( \alpha^{10} \), and the factor \( g_7(x) \) has roots \( \alpha^7, \alpha^{14}, \alpha^{13}, \) and \( \alpha^{11} \). Thus we can choose either \( j = 5 \) or \( j = 7 \), corresponding to \( f(x) = g_5(x) \) or \( g_7(x) \). Let us suppose further that we wish to correct a single left-shift or right-shift error, so that \( t_l = t_r = 1 \), and therefore \( t_s = 2 \). The final requirement on \( j \) is that \( t_s < n_1 \) where \( n_1 \) is the order of \( \alpha^j \). Now both \( g_5(x) \) and \( g_7(x) \) satisfy \( 2 = t_s < n_1 \), since the order of \( \alpha^5 \) is 3 and the order of \( \alpha^7 \) is 15. Thus \( g_5(x) \) and \( g_7(x) \) are both acceptable choices for \( f(x) \). However, in order to add as little redundancy as possible for synchronization purposes, we choose for \( f(x) \) the acceptable polynomial of least degree satisfying \( t_s < n_1 \). Hence we take \( f(x) = g_5(x) \). Thus the subcode \( C^* \) has the generator polynomial
\[
g^*(x) = g(x)g_5(x)
\]
\[
= (1 + x^4 + x^6 + x^7 + x^8)(1 + x + x^2)
\]
\[
= 1 + x + x^2 + x^4 + x^5 + x^8 + x^{10}
\]
and \( C^* \) is thus an \((n, k^*) = (15, 5)\) code. The subcode \( C^* \) has the roots
\[
\alpha, \alpha^2, \alpha^3, \alpha^4, \alpha^5, \alpha^6, \alpha^8, \alpha^{10}, \alpha^{12}.
\]
Such a code, if used solely for additive-error correction, would be a 3-additive-error correcting BCH code, since the first six successive powers
of $\alpha$ are roots of $C^*$. The generator matrix of $C^*$ is given by

$$G^* = \begin{bmatrix}
1 & 1 & 1 & 0 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 1 & 1 & 1 & 0 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 1 & 1 & 0 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 1 & 1 & 0 & 1 & 1 & 0 & 0 & 1 & 0 & 1 \\
0 & 0 & 0 & 0 & 1 & 1 & 1 & 0 & 1 & 1 & 0 & 0 & 1 & 0 & 1
\end{bmatrix}.$$  

The code $C$ is the null space of the matrix $H_0$ given by

$$H_0 = \begin{bmatrix}
1 & \alpha & \alpha^2 & \alpha^3 & \cdots & \cdots & \alpha^{14} \\
1 & \alpha^3 & (\alpha^3)^2 & (\alpha^3)^3 & \cdots & \cdots & (\alpha^3)^{14} \\
1 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 1 \\
0 & 1 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 1 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 1 & 1 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 1 & 1 \\
0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 1 & 1 \\
0 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 1 \\
0 & 1 & 1 & 1 & 1 & 0 & 1 & 1 & 1 & 1 & 0 & 1 & 1 & 1 & 1
\end{bmatrix}.$$  

We note that $H_0$ has $r = n - k = \deg [g(x)] = 8$ rows, so that the parity check matrix of $C$ is equal to $H_0$. The matrix $H_1$ is given by

$$H_1 = [1, \beta, \beta^2, \cdots, \beta^{13}, \beta^{14}] = [1, \alpha^5, (\alpha^5)^2, \cdots, (\alpha^5)^{13}, (\alpha^5)^{14}] = \begin{bmatrix}
1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 \\
0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 \\
0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}.$$
We can see from this matrix that, as noted earlier, the order of \( \beta \) is 3, i.e., \( \beta^3 = (1, 0, 0, 0) \). Note that the last row of \( H_1 \) is null, and the second and third rows are identical so that \( H_1 \) is not of full rank. The rank of \( H_1 \) is in fact, equal to \( \deg [g_b(x)] = 2 \). To encode a \( k^* \)-coordinate information vector \( s' = (s_0, s_1, \ldots, s_{k^*-1}) \) into a codeword of \( C^* \), we make the vector \( s' \) correspond to the codeword \( v' = s' G^* \). [Equivalently, we make the information polynomial
\[
s(x) = s_0 + s_1 x + s_2 x^2 + \cdots + s_{k^*-1} x^{k^*-1}
\]
correspond to the code polynomial \( s(x)g^*(x) \).] For example, the vector \( (10110) \) is encoded into \( (10110) G^* = (110010100001110) \). Table 2 contains a list of the 32 possible information vectors, \( s' \), and the corresponding codewords of \( C^* \).

Since \( t_l = 1 \) and \( t_r = 1 \), the words of the augmented subcode \( C_a \) are obtained by adjoining the initial symbol of each word of \( C^* \) to the end of the word, and adjoining the final symbol to the beginning.

We now must determine a choice for the translation vector \( c' \). Suppose that we choose \( c' = g' \), where \( g' = (100101110000000) \) is the coefficient vector of \( g(x) \), considered as a polynomial of degree 14. Then we have
\[
c_a' = (010001011100000001),
\]
and we may formally write
\[
C_t = C_a + c_a',
\]
since each word of \( C_t \) corresponds to the sum of \( c_a' \) and a word of \( C_a \). The words of the code \( C_t \) are shown in Table 2. The code \( C_t \) is an \((n_t, k_t) = (17, 5)\) code. It is the words of \( C_t \) that are sent over the channel.

The code \( C_t \) can correct \( t = 2 \) additive errors (since \( C \) is a 2-additive-error-correcting BCH code) and \( t_r = 2 \) synchronization errors, and may be called a \((t, t_r) = (2, 2)\)-error-correcting code. The error-correction procedure is illustrated below.

Suppose that the source has generated the information vector \( s' = (10110) \). The word in \( C^* \) corresponding to \( s' = (10110) \) is \( v' = (110010100001110) \), and the corresponding word in \( C_t \) is \( v_t' = (00100000011001110) \). Thus the word \( v_t' = (00100000011001110) \) is sent over the channel. Suppose that a left-shift error of order 1 has occurred, so that if no additive errors occurred, the sequence \((01000001100111001)\) would be received, where we have assumed for

</tbody>
</table>

definiteness that the first symbol in the word following \(v_t'\) was 1. In addition to the synchronization error, however, let us suppose that two additive errors occurred, so that the third and twelfth symbols of \((001000001100111001)\), or the second and eleventh symbols of
(01000001100111001), were complemented. Thus
\[ y'_a = (01000001100111001) + (01000000001000000) \]
\[ = (00000001101111001) \]
is the received word. The receiver drops the first and last symbols of
\( y'_a \) (i.e., the first \( t_r \) and last \( t_l \) symbols, with \( t_r = t_l = 1 \)), to obtain
\[ y' = (000000110111100). \]
The receiver then calculates the additive-error syndrome
\[ y'H' = (11010111). \]
Since the additive-error syndrome is nonzero, the receiver interprets that
an additive error has occurred, and proceeds to correct it. To do this, the
receiver would employ one of the known procedures for correcting ad-
ditive errors for the BCH code \( C \), using the syndrome \( (11010111) \).
Since we have
\[ (100000000100000)H' = (11010111), \]
the receiver would reach the conclusion that the additive-error pattern
in \( y' \) is
\[ e' = (100000000100000). \]
The receiver then calculates the corrected vector
\[ z' = y' - e' \]
\[ = (000000110111100) - (100000000100000) \]
\[ = (100000110011100). \]
Next it calculates the synchronization-error syndrome
\[ z'H'_1 = (0110) = \alpha^5. \]
The receiver must now use this synchronization-error syndrome to deter-
mine which synchronization error, if any, has occurred.
To do this it calculates
\[ \xi = c'H'_1 = (1110) = \alpha^{10}. \]
Now
\[ z'H'_1/\xi = \alpha^5/\alpha^{10} = \beta^2; \]
thus
\[ \beta^u = \beta^g \quad \text{or} \quad u = 2 > 1 = t_e. \]

Hence the receiver interprets that a left-shift error of order \( L = n_1 - u = 3 - 2 = 1 \) has occurred, and moves the word marks one place to the left.

Hence the truncated received word, corrected for additive and synchronization errors, is
\[ z^e = (010000011001110). \]

Subtracting \( c' \), the receiver correctly interprets that
\[ v = z^e - c' = (010000011001110) - (100010111000000) \]
\[ = (110010100001110) \]
is the word of \( C^* \) corresponding to the transmitted word. Hence the information symbols are correctly interpreted as \( s' = (10110) \).

Because of the seriousness of synchronization errors, the receiver should not take corrective action upon observing the first indication (from the synchronization-error syndrome) that a synchronization error has occurred. For proper use of the technique, the truncated received word must not itself contain the synchronization error. Thus the first word after the word containing the synchronization error gives the first reliable indication of the occurrence of the synchronization error. Words actually containing symbol gains or losses are severely altered and may result in nonzero, but false, synchronization error syndromes. Also, if more than \( t \) additive errors occur, a nonzero synchronization-error syndrome may result even though there has been no synchronization error. The importance of making correct decisions regarding synchronization errors warrants the observation by the receiver of the same synchronization-error syndrome for several successive words before correcting the apparent synchronization error. Of course, if the receiver destroys synchronization by taking corrective action corresponding to a spurious nonzero synchronization-error syndrome resulting from the occurrence of more than \( t \) additive errors, then this mistake will be rectified with the next received word containing not more than \( t \) additive errors.
